# Post-18 education - who is taking the different routes and how much do they earn? 

Héctor Espinoza, ${ }^{* \$}$ Stefan Speckesser, ${ }^{*+\wedge}$ Imran Tahir, ${ }^{\&}$ Jack Britton,\& Sandra McNally,*\$~ Anna Vignoles^@<br>*Centre for Vocational Education Research (CVER); \$Centre for Economic Performance, London School of Economics; +National Institute of Economic and Social Research; ^University of Brighton; ${ }^{\circledR}$ Institute for Fiscal Studies; ~University of Surrey; @University of Cambridge

## Key findings

- We describe the educational trajectories and labour market outcomes for people who completed their GCSEs between 2002 and 2006. Our long span of longitudinal data enables us to follow these individuals through their schooling and beyond into their early careers.
- Only around $4 \%$ of those with at least a Level 3 qualification by age 19 gain a Level 4,5 or foundation degree qualification as their highest qualification by age 25 . Conversely, almost two-thirds achieve Level 6 as their highest qualification by the same age.
- Foundation degrees are often used as stepping stones to getting degrees. Around half of those who do foundation degrees also complete a degree by age 25 . They almost always do so in the same subject.
- Similarly, around one-third of those who obtain Level 4 or Level 5 qualifications also obtain degrees by age 25 . For the small number who combine Level 4 and Level 6 qualifications, it is just as common to do the Level 4 qualification after the degree as doing it before.
- People whose highest level of education is Level 4, Level 5 or a foundation degree have much lower prior attainment (as measured by GCSE scores taken at age 16) than people who do degrees.
- Subject choices for sub-degree-level qualifications are very different for men and women. Men are much more likely to be doing engineering \& technology; architecture, building \& construction (e.g. planning); or computing, while women are more likely to be doing business \& administration or nursing. Foundation degrees in creative arts are also quite common.

We estimate 'returns' to the different qualification routes. Identifying the causal impact on earnings from taking the different qualification routes is difficult. Taking Level 4 and 5 qualifications was not (and still is not) a typical trajectory for young people, meaning the people we observe taking these routes are likely to be different from people who did not in ways that
are difficult to control for (i.e. the estimated returns could be affected by selection bias). We report our key findings on the earnings outcomes with this caveat very much in mind:

- All higher-level qualifications appear to lead to better earnings outcomes than finishing education at Level 3 for both men and women. Yet there is a great deal of variation in the magnitude of these estimates across the different qualifications taken and by gender.
- For women, completing a Level 5 qualification leads to the highest average return at the age of 26 . Female Level 5 achievers (Level 5 only) earn approximately 45.2 log points ( $57 \%$ ) more than stopping at Level 3 after adjusting for observable differences between the two groups. This equates to roughly a $£ 9,800$ increase in annual earnings at age 26 , compared with average earnings of $£ 17,000$ from completing education at Level 3.
- For men, Level 4 qualifications lead to the highest average return at the age of 26. On average, these qualifications are associated with earnings at age 26 around $£ 9,000$ higher than for men who complete their education at Level 3. This means that male Level 4 achievers (Level 4 only) earn roughly 35.4 log points ( $42 \%$ ) more at age 26 than men who complete their education at Level 3 , after adjusting for observable differences.
- While the returns to university degrees relative to stopping education at Level 3 appear to be good, it is very notable that they are lower than male Level 4 and female Level 5 estimates. However, the relative earnings differential between these qualifications becomes smaller between the ages of 26 and 30 . This, combined with evidence from other sources (e.g. Britton et al. (2020) ${ }^{1}$ highlighted the large earnings growth of higher education graduates during their 30s) suggests that this gap will be smaller and may indeed reverse at later ages.
- The results are also heavily determined by some specific subject areas. For these reasons, it should not be assumed that massive expansion of sub-degree-level qualifications will yield similar returns to those reported here, especially if in different subject areas.

[^0]
## 1. Introduction

After finishing compulsory education, young people in England have a range of higher education (HE) and further education (FE) options available to them. While people are familiar with the route taken by most HE learners - completing A Levels and then a degree at university - less is commonly understood about FE at tertiary level. In this note, we address this by describing the educational routes taken by individuals who choose to pursue tertiary-level FE courses. Additionally, we show how learners in different post-18 education routes differ by prior attainment, age and gender.

As well as presenting descriptive evidence, we examine the association between different educational pathways and future earnings. Specifically, we present estimates of the early-labourmarket returns (at age 26 and age 30) associated with different levels of post-18 qualifications. We find that, on average, certain FE qualifications, such as Level 4 qualifications for men and Level 5 qualifications for women, are associated with higher average early-labour-market earnings than completing a degree. We find that these patterns hold even once we condition on observable characteristics. Whilst we use the term 'returns', we are careful not to claim that these estimates capture the causal impact of taking these qualifications, as there may be other factors that we do not observe that may potentially account for selection of different individuals into the different routes.

This note is structured as follows. We begin by introducing the data and sample used in our study. Next, we present our emerging findings on the different routes taken through post-18 education, as well as the characteristics of learners in different routes. Finally, we investigate earnings outcomes for the different post-18 routes and what happens to those earnings outcomes once we condition on observable characteristics of the people taking them.

## 2. Data and sample

We use data on five cohorts of secondary school leavers in England who completed their compulsory education between $2001 / 02$ and $2005 / 06$. For each of these individuals, we have compiled an education record from school through to FE and HE using data from three education registers - the National Pupil Database (NPD), the Individualised Learner Record (ILR) and Higher Education Statistics Agency (HESA) data. ${ }^{2}$ We add earnings from HMRC tax records to these education records, which enables us to investigate how returns vary by post-18 qualification route.

In the empirical analysis that follows, we focus on a subset of state-school students in these five cohorts who are likely to have the option of studying higher-level courses. This restriction ensures a degree of comparability in the underlying characteristics of different learners for our empirical

[^1]analysis. Specifically, we consider individuals who completed their GCSEs between 2001/02 and 2005/06 and meet the following conditions:

1. They have obtained at least five $A^{*}-C$ GCSE grades and have achieved a Level 3 qualification by the age of 19 .
2. They have post-compulsory education records (from the NPD Key Stage 5, ILR or HESA data).
3. They have earnings data available (from HMRC tax records).

Table 1 presents the sample size broken down by GCSE cohort and sample restriction. Column 1 gives the total number of state-school students in each cohort, and column 2 shows the number of students in each cohort that have achieved at least five 'good' GCSEs and Level 3 by the age of 19. Column 3 displays the number of students from column 2 for whom we are also able to match post-16 educational records from at least one source. Column 4 shows individuals with both post-16 educational and earnings records. In column 5, we additionally exclude individuals whose highest qualification is an apprenticeship or a postgraduate degree, as well as people with post-18 courses in more than two levels. ${ }^{3}$ Lastly, column 6 reports the sample we use for analysis, which additionally removes individuals who do not have any positive reported earnings between the ages of 25 and 30 .

## 3. Emerging findings on the routes taken and characteristics of post-18 learners

As well as estimating returns/earnings premiums, we seek to better understand the nature of higher-level (Level 4 and above) post-18 education in England. Here we focus on presenting evidence on two aspects of post-18 education for our sample of learners: (i) the education routes taken by learners in higher-level post-18 education and (ii) the characteristics of these learners.

## (i) Routes taken by those in higher-level (Level 4 and above) post-18 education

A range of qualifications and routes are available to individuals who wish to progress from their Level 3 qualification. Table 2 presents the number of learners in our final sample who have progressed beyond Level 3 and have completed one or a combination of higher-level (Level 4, 5, 6 and foundation degrees) qualifications by the age of 25 .

Table 2: The higher educational qualifications achieved by age $\mathbf{2 5}$ for individuals in the final earnings sample who progress beyond Level 3 qualifications

|  | Level 4 | Level 5 | Foundation <br> degree | Level 6 |
| :--- | :---: | :---: | :---: | :---: |
| Learners with <br> qualification <br> at one level | 12,083 | 12,966 | 11,071 | 575,129 |
|  | Level 4 plus ... | $/$ | 891 | 406 |
| Learners with <br> qualifications <br> at two levels | Foundation <br> degree plus ... | 891 | $/$ | 59 |
|  | Level 6 plus ... | 5,197 | 6,321 | 13,199 |
| Total in each level | 18,577 | 20,237 | 24,735 | 59,321 |

Source: Linked NPD-ILR-HESA-HMRC data, from column 6 of Table 1 (excluding those with Level 3 only). Some individuals appear in more than one column in the bottom row.

Most importantly, Table 2 shows that only a small number of people in our sample complete higher-level FE courses compared with the number that complete a degree. Only around $6.5 \%$ of the sample (the state-educated students with a Level 3 qualification by age 19, a post-compulsory education record and at least one positive earnings record between 25 and 30) achieve Level 4, 5 or foundation degree qualifications by age 25 (including those who subsequently go on to Level 6).

Further, it is common for individuals who complete a higher-level vocational course or foundation degree to combine these with other qualifications. By far the most common of these combinations is to combine a lower-level qualification with a Level 6 qualification. As a result, only around $4 \%$ of the sample have a highest qualification of Level 4, Level 5 or a foundation degree, while
$63 \%$ have a highest qualification of Level 6 (recall, postgraduate students are excluded entirely). The remaining third of the sample do not achieve a higher qualification than Level 3.

Figure 1: Number of learners who complete a Level 4 / Level 5 / foundation degree qualification plus a Level 6 qualification by the age of 25

Source: Linked NPD-ILR-HESA-HMRC data.

Figure 1 summarises the combination of qualifications further. It shows that roughly onethird of those achieving Level 4 and Level 5 qualifications also obtain degrees by age 25 . Perhaps unsurprisingly, the share achieving a degree of those who do foundation degrees is higher at just over $50 \%$. This suggests that learners often use FE courses as a stepping stone to a degree. Indeed, 86\% of learners combining Level 5 with Level 6 qualifications, and $93 \%$ of learners completing foundation degrees and Level 6 qualifications, make the sequential progression from the lower qualification to a degree. However, a different pattern is observed amongst those combining Level 4 with Level 6: only around $44 \%$ achieve Level 4 qualifications first and then a Level 6 qualification. So for those with both a Level 4 and a Level 6 qualification, slightly more than half are doing the degree-level qualification first. ${ }^{4}$ It is worth keeping in mind though that the overall numbers here are small (only around 5,000 people combine Level 4 and Level 6 qualifications in our sample, compared with around 575,000 people who have a qualification at Level 6 only).

[^3]Figure 2 highlights the subject areas studied by these learners with combined qualifications (those who have completed an FE qualification plus a degree). We see that the majority of these learners do their degree in the same subject area as their FE course, even though this is less common for those who combine Level 4 and Level 6 qualifications. This suggests Level 5 and foundation degree qualifications are being used as potential stepping stones to a degree in the same subject area.

Figure 2: Percentage of learners who complete their advanced FE qualification and degree in the same subject area

Source: Linked NPD-ILR-HESA-HMRC data.

## (ii) The characteristics of different higher-level (Level 4 and above) post-18 learners

## Prior attainment

Figure 3 takes a closer look at the GCSE attainment of different learner groups within the 2006 GCSE cohort. ${ }^{5}$ For each level of education achieved by age 25, we show the distribution of a standardised GCSE score. The key message from this figure is that individuals with below degreelevel attainment by age 25 are similar in terms of GCSE attainment, but degree-holders tend to have performed significantly better in their GCSEs.

[^4]Figure 3: GCSE points (z-scores) distribution by highest level of education achieved by age 25

Source: Linked NPD-ILR-HESA-HMRC data. Sample based on final column of Table 1.

## Age obtaining qualifications

Figure 4 shows that degrees are mostly completed by people between the ages of 21 and 22 , whereas there is more variation in the age at which people complete other qualifications. It is more common for individuals to complete Level 4 and foundation degrees by age 21, whereas Level 5 learners tend to complete their qualifications at a later age. This diversity of progression patterns is likely to be related to different labour market experiences and different types of qualifications studied, and hence comparisons of earnings at a given age need to take account of this fact.

Figure 4: Age at which learners complete FE and HE qualifications

Source: Linked NPD-ILR-HESA-HMRC data. Sample based on final column of Table 1.

## Subjects studied

Tables 3 and 4 show that, compared with HE learners, FE learners are predominantly concentrated in relatively few subject areas. This reflects individuals' demand for courses but also that sub-degree courses tend to be offered in a narrower range of subject areas. (In Appendix A2, we provide a breakdown of the numbers studying each subject area by gender.)

There are clear differences in subject choices between men and women. At Level 4, more than three-quarters of men study engineering \& technology, architecture, building \& construction (e.g. planning) or business \& administration. Women are around twice as likely to study business \& administration at Level 4 ( $40 \%$ vs $18 \%$ ) but are much less likely to take the former subjects. Instead, nearly $30 \%$ of women study education at Level 4. At Level 5, around 70\% of women study 'subjects allied to medicine' - mostly nursing - versus just 12\% of men, while men are more likely to be doing engineering or computer science courses. At foundation degree level, computer science is again more popular for men, while women are more likely to be studying education. At this level, creative arts courses are common for both men and women. The gender balance of subject choices is more equal at Level 6 than at lower levels, and a far broader range of subjects are studied at Level 6.

Table 3: Percentage of males taking qualifications in selected subject areas by level

| Subject area | Level 4 | Level 5 | Foundation <br> degree | Level 6 |
| :--- | :---: | :---: | :---: | :---: |

## 4. Earnings outcomes for FE and HE qualifications

We now turn to investigate the earnings outcomes for people who took different post-18 education routes. We first outline our methodology and then present estimates of the effect of different post-18 qualifications on early-career earnings. Estimates have a causal interpretation under the assumption that there are no unobserved factors that influence both the choice to pursue a given educational pathway and future labour market outcomes. Although we control for many relevant variables, as we have already highlighted this remains a strong assumption. Results should be interpreted with this caveat in mind: positive earnings outcomes from certain routes amongst the people who chose to take them would not necessarily translate into positive outcomes for others (the majority) who did not. It is also important to bear in mind that we are estimating returns for individuals at an early point of their career; individuals pursuing different trajectories may have a very different pattern of returns over their lifetime. ${ }^{6}$

[^6]
## Methodology

We use regression analysis to estimate the average monetary returns from different educational routes relative to stopping education at Level 3.7 Regression analysis enables us to calculate the earnings from different educational routes relative to finishing at Level 3 while accounting for underlying differences between learners in observable factors, such as socioeconomic status and prior attainment. Here we describe the two main steps in our estimation strategy, ${ }^{8}$ but more detail is provided in Appendix A3.

## Defining qualification groups

Our empirical analysis begins by classifying each individual in our sample into a given educational route according to their trajectories up to age 25 . We calculate the difference in returns relative to finishing at Level 3 for 10 different education routes:

1. Level 4 only
2. Level 4 and Level 5 (excluding foundation degrees)
3. Level 4 and a foundation degree
4. Level 4 and Level 6
5. Level 5 only
6. Level 5 and a foundation degree
7. Level 5 and Level 6
8. foundation degree only
9. foundation degree and Level 6
10. Level 6 only

In most cases, there are sufficient numbers of people in these groups to detect statistically significant differences in earnings from those leaving education with only Level 3 qualifications, but there are some exceptions. Specifically, there tend to be too few observations for individuals combining Level 4 with foundation degrees and individuals combining Level 5 with foundation degrees.

## Statistical analysis of differences in earnings between qualification groups

The overall goal is to study the effect that completing each of these qualifications has on earnings. However, as has been said, there is likely to be a substantial amount of selection into the different education routes. We can deal with this to an extent using a regression-based approach that

[^7]controls for observable characteristics of the people taking each of the education paths, such as prior attainment and socio-economic status. Variables such as these are likely to affect both an individual's qualification group and their future earnings (for a description of this approach, see Appendix A3). Although this is likely to bring us closer to the true causal estimates of each route than the unconditional earnings differences would, it is unlikely that the final estimates using this regression approach will fully account for the selection into different routes. Nevertheless, we think that much can be learned from this exercise.

## Findings

We report our regression estimates at age 26 and age 30 for both men and women, ${ }^{9}$ in Tables 5 and 6 respectively. In each case, the unconditional results do not control for anything other than cohort and report the log-point differences (approximately, the percentage differences) in earnings of each of the qualification groups relative to the base group of Level 3 only (noting that this is based on completed qualifications only). The conditional results control for a very simple measure of labour market attachment, ${ }^{10}$ prior attainment and background characteristics. ${ }^{11}$ The full regression results are presented in Appendix A4 (Tables A4.1 and A4.2) and show the impact of the sequential addition of the control variables. The tables do not present estimates for the returns to Level 4 plus a foundation degree and Level 5 plus a foundation degree, because we do not observe a sufficient number of individuals completing these two qualification combinations to be able to accurately estimate returns.

The raw earnings premiums for some FE qualifications are high. For example, for women, the unconditional earnings of the Level 5 group are 44.1 log points (55\%) above the Level 3 only group at age 26 (for men, the equivalent figure is 11.2 log points, or $12 \%$ ). We see that in most cases the conditioning variables do not substantially change the raw estimates. However, this is not the case for the Level 6 only group. For women, the unconditional earnings of the Level 6 only group are 28.7 $\log$ points (33\%) above the Level 3 only group at age 26 , while the conditional earnings are only 18.6 $\log$ points (20\%) higher. Similar drops in the estimates occur at age 30 and for men. Overall, this is unsurprising given the much higher prior attainment of those doing Level 6 qualifications relative to all of the other groups. ${ }^{12}$

Standard errors in parentheses, ${ }^{*} \mathrm{p}<0.05,{ }^{* *} \mathrm{p}<0.01,{ }^{* * *} \mathrm{p}<0.001$. Significance is relative to Level 3 qualifications. There is insufficient sample to estimate L5 + FD and L4 + FD. 'Uncond.' indicates unconditional estimates, while the 'Cond.' estimates control for a simple measure of labour market attachment, prior attainment, student background, and school and local authority fixed effects.

We use the regression results to calculate expected earnings for individuals with different qualifications at ages 26 and 30. These are reported in Table 7. It should be noted that these are average numbers and there will of course be considerable variation around these averages for different individuals (as indicated by the standard errors in Tables 5 and 6). Figures 5 and 6 show the same information for age 30 but as average earnings differences from the base case of Level 3 only. For each qualification, we show both the raw (unconditional) and conditional (when we include all controls) differences, relative to the base case of Level 3 only.

Table 7: Regression-adjusted average earnings (to nearest $\mathbf{£ 1 0 0}$ ) for different qualification combinations at age 26 and at age 30

|  | Age 26 earnings <br> (to the nearest hundred) |  | Age 30 earnings <br> (to the nearest hundred) |  |
| :--- | :---: | :---: | :---: | :---: |
|  | Women | Men | Women | Men |

Figure 6: Age 30 unconditional and conditional cash returns relative to Level 3 only for men (Level 3 average $=\mathbf{£ 2 8 , 0 0 0 )}$

Notes: Draws on age 30 regression results from Table 6. Also see notes to Table 6.

To summarise our main findings, at age 26, we find that:

- All higher-level qualifications appear to lead to better earnings outcomes than finishing at Level 3, for both men and women. Yet there is a great deal of variation in the magnitude of these estimates across the different qualifications taken and by gender.
- For women, completing a Level 5 qualification leads to the highest average return at the age of 26. Female Level 5 achievers (Level 5 only) earn approximately $45.2 \log$ points (57\%) more than stopping at Level 3 after adjusting for observable differences between the two groups. This equates to roughly a $£ 9,800$ increase in annual earnings at age 26 , compared with average earnings of $£ 17,000$ from completing education at Level 3.
- For men, Level 4 qualifications lead to the highest average return at the age of 26 . On average, these qualifications are associated with earnings at age 26 around $£ 9,000$ higher than for men who complete their education at Level 3. This means that male Level 4 achievers (Level 4 only) earn roughly $35.4 \log$ points (42\%) more at age 26 than men who complete their education at Level 3, after adjusting for observable differences.
- Amongst both males and females, Level 4 and Level 5 achievers and those combining these qualifications with other high-level qualifications appear to have an early advantage compared with degree-holders (Level 6 only).
- Foundation degrees and Level 3 qualifications show comparable earnings returns for women. For men at age 26, foundation degrees lead to only a small return over finishing at Level 3. Foundation degrees combined with degrees do not fare a great deal better at this relatively early stage.

At age 30, we observe similar patterns:

- Males achieving Level 4 qualifications show relatively high returns. Men with a Level 4 qualification at age 30 (Level 4 only) have average earnings that are $£ 9,000$ higher than men qualified to Level 3, after adjusting for observable differences. Females achieving Level 4 qualifications also show strong conditional earnings returns.
- There are especially high estimates amongst females achieving Level 5, but the magnitude of these relative to other qualifications is smaller than at age 26.
- Degree-holders have consistently higher conditional earnings estimates than those who completed Level 3 only. Perhaps surprisingly, these are lower than male Level 4 and female Level 5 estimates. However, it is crucial to note that the relative earnings differential between these qualifications becomes smaller between the ages of 26 and 30 . Evidence from other
sources (Britton et al., 202015) highlight the large earnings growth of higher education graduates during their 30 s, suggesting that this gap could indeed continue to shrink.

From our results, we see that Level 4 qualifications are associated with especially high earnings for men and Level 5 qualifications are associated with especially high earnings for women, and this holds true even once we adjust for observable characteristics. While we cannot perfectly adjust for selection into the different routes, this result is important as it suggests that for some groups of people these qualifications can lead to very good earnings outcomes.

## The importance of subject

Connecting back to statistics reported in Tables 3 and 4, it is important to note that subject choices are likely to play an especially important role here. In Table 8, we show the most common qualifications taken at Level 4 and Level 5 by individuals in our sample.

Around $38 \%$ of the Level 4 learners in our sample have HNCs in engineering (25\%) or building/construction (13\%), and the majority of these learners are male. Around $50 \%$ of those who complete Level 5 qualifications take a DipHE in nursing, and the majority of these learners are female. Both sets of qualifications are likely to lead to occupations with high returns relative to occupations that are available to learners stopping at Level 3. Therefore, as well as labour market attachment and individual characteristics, the subject choices made within Level 4 and Level 5 qualifications play a big part in explaining our observed pattern of estimates. As a result, one should not assume that the same outcomes would be achieved for people studying at the same qualification level but in different fields. Moreover, one should bear in mind that the number of individuals with these qualifications is extremely small and one would expect the earnings outcomes to change if the inflow greatly increased.

Table 8: The most common qualifications at Level 4 and Level 5

|  | Qualification name | Percentage of learners <br> in each level taking the <br> qualification | Percentage of <br> learners taking the <br> qualification that are <br> female |
| :---: | :---: | :---: | :---: |
| Level 4 | HNC in engineering ${ }^{16}$ | $25 \%$ | $5 \%$ |
| Level 4 | HNC in building/construction | $13 \%$ | $9 \%$ |
| Level 5 | DipHE in nursing | $50 \%$ | $92 \%$ |

## 5. Conclusion

In this note, we have used evidence from the combined education and earnings records of five cohorts of students who completed their GCSEs in England between 2002 and 2006 to study the routes taken and outcomes realised by sets of post-18 learners. We have shown that by the age of 25 , a comparatively small number of individuals in these cohorts complete tertiary-level FE qualifications compared with the numbers who complete degrees. Moreover, individuals who pursue tertiary FE qualifications differ from those who only complete HE qualifications. First, they differ by the educational routes they take, as it is common for FE learners to combine multiple qualifications and study FE qualifications in comparatively few subject areas. Second, they differ in their underlying characteristics, as degree-holders tend to have much higher levels of prior attainment.

We have also presented unconditional and conditional earnings estimates for the early-labourmarket returns (at age 26 and age 30) associated with different FE and HE qualifications. We find that certain FE qualifications, such as Level 4 FE qualifications for men and Level 5 FE qualifications for women, lead to higher early-labour-market earnings on average than completing a degree, once we adjust for observable characteristics of those taking the different routes. We suggest that these results may be explained to a large extent by specific high-value subject areas that account for large shares of individuals within a given qualification level. Most notably, a high share of Level 4 learners are men completing qualifications in engineering or construction, whereas large shares of Level 5 learners are women who have completed qualifications in nursing. More generally, the estimated earnings differentials between university degrees and higher-level vocational education suggest that vocational qualifications can be a route to positive labour market outcomes.

The estimates we produce should be treated with caution for several reason. First, we are not fully able to control for selection into the different FE and HE routes, meaning that we cannot assume (for example) that individuals selecting into a Level 5 qualification would have achieved the same return to Level 6 as the average student if they had made a different choice. Second, the results are based on fairly small numbers of people selecting into Level 4 and 5 qualifications compared with a much large number of people with either Level 3 or Level 6 as their highest qualification level. Third, we do not observe some sources of earnings heterogeneity, such as an individual's occupation or the industry in which they work, and so we are unable to compare the earnings of people within the same job types. Fourth, it is crucial to consider how different educational trajectories prepare people for a lifetime in the labour market and whether they enable individuals to cope with technical change and economy-wide shocks. To explore this issue further, research investigating the difference in the earnings return to these different qualifications in mid and later career is required. Although our estimates are based on the most recent earnings data available, it may well be that with changes in the labour market, estimated returns may differ for individuals currently taking these qualifications. For example, radical reform either in how different routes are rewarded (e.g. in health and social
care) or in labour market demand for skills (e.g. through increased mechanisation) may well lead to important changes in the return to different educational trajectories.

Nevertheless, the estimated earnings differentials between university degrees and higher-level vocational education provide useful information for young people and for public policy. Despite the important caveats, it seems that sub-degree-level qualifications can lead to good outcomes for the young people well suited to those qualifications. This is especially relevant as the duration of vocational courses is typically shorter and so the financial cost to the exchequer and the opportunity cost to individuals are also lower (which are factors we do not account for in our calculations). Further, as well as labour market returns from such qualifications, many individuals appear to use them to progress within higher-level tertiary education and it is also important to maintain such progression possibilities in future reforms.

## Appendix

## A1: Summary statistics for all learners in the 2006 GCSE cohort

Table A1.1: Highest level of educational attainment (by level) and earnings at age 26

| Highest level of <br> educational <br> attainment at 26 | Frequency | Average earnings at <br> 26 (nearest $£ 100$ ) | Average earnings at <br> 26 (positive earnings <br> only and nearest <br> $£ 100)$ |

## A3: Estimating comparable FE and HE returns

We estimate the earnings returns to different qualifications using regression analysis on the education and earnings data of our final earnings sample. As we set out in Section 2, this sample includes state-school pupils from the five GCSE cohorts between 2001/02 and 2005/06 who obtained at least five A*-C GCSE grades and achieved a Level 3 qualification by the age of 19 .

We estimate the following two regression models separately for males and females:

$$
\begin{aligned}
& \text { (1) } \log (\text { age } 26 \text { earnings })=\alpha+\beta^{\prime} \text { Qualification }+X^{\prime} \gamma+\epsilon \\
& \text { (2) } \log (\text { age } 30 \text { earnings })=\alpha+\beta^{\prime} \text { Qualification }+X^{\prime} \gamma+\epsilon
\end{aligned}
$$

Dependent variables - We estimate our model using log-earnings at age 26 for all five GCSE cohorts and log-earnings at age 30 for just the 2001/02 GCSE cohort (this is the only cohort for which we have age 30 earnings available).

Variable of interest (Qualification) - We include 10 dummy variables for the highest qualification level achieved by age 25 for each individual:

1. Level 4 only
2. Level 4 and Level 5 (excluding foundation degrees)
3. Level 4 and a foundation degree
4. Level 4 and Level 6
5. Level 5 only
6. Level 5 and a foundation degree
7. Level 5 and Level 6
8. foundation degree only
9. foundation degree and Level 6
10. Level 6 only

The omitted dummy in our model is Level 3 only, which means the reference/baseline group for the regression results is individuals whose highest qualification level at age 25 is Level 3.

Independent variables $\boldsymbol{( X )}$ - We estimate five specifications of our model, with each specification containing an additional set of control variables. The sets of controls, which we indicate at the bottom of the results tables in Appendix A4, are as follows:

- We include a variety of measures of background characteristics, including free school meal (FSM) eligibility, English as an additional language (EAL) status, ethnicity, and a measure of socio-economic status calculated using local-area deprivation statistics.
- We control for previous attainment at both Key Stage 2 (KS2) and Key Stage 4 (KS4). We measure KS2 attainment using performance on English and Maths tests at the end of KS2; KS4 attainment is captured by an individual's total KS4 points score.
- We include a simple measure of labour market attachment that records whether we observe the individual in paid employment in the previous period (i.e. whether or not we observe positive employment earnings at age 25 or age 29).
- Lastly, we include controls for two sets of fixed effects - (GCSE) cohort fixed effects and (secondary) school fixed effects.

## A4: Regression results

Table A4.1: The effect of completing qualifications (relative to finishing at Level 3) on earnings at 26 for the 2002 to 2006 GCSE cohorts

| Dep. variable: In earnings age 26 |  |  |  |  |  |  | Dep. variable: In earnings age 26 |  |  |  |  |

${ }^{17}$ The size of the final regression sample ( 800,104 observations) is smaller than the final earnings sample reported in Table 1 ( 959,329 observations) for three reasons: (i) only individuals with positive reported earnings at age 26 are included in the regression sample; (ii) individuals with key missing variables are omitted from the regression sample; and (iii) we exclude individuals with extreme earnings (i.e. below the $1^{\text {st }}$ percentile and above the $99^{\text {th }}$ percentile) from the regression sample.

Table A4.5 shows the conditional probability of being employed at age 26 for the 2002 to 2006 GCSE cohorts based on educational attainment (relative to finishing at Level 3). The binary dependent variable Employed is defined by observing (or not) positive income at age 26 in the HMRC data. In the context of a probit model, the marginal effects show how the conditional probability of employment changes by qualification types compared with finishing at Level 3, holding all other regressors constant. ${ }^{18}$ Overall, we find that men and women achieving higher-level qualifications are 1-3\% more likely to be employed, compared with the reference group. High employment ratios are observed in all cases (i.e. above Level 3), ranging from $86 \%$ to $90 \%$.

Table A4.6 shows the conditional probability of being employed at age 30 for the 2002 GCSE cohort based on educational attainment (relative to finishing at Level 3). The binary dependent variable Employed is defined by observing (or not) positive income at age 30 in the HMRC data. ${ }^{19}$ Amongst women, those with higher-level qualifications are still $2-5 \%$ more likely to be employed at age 30 , compared with the reference group. For men, there are no differences between qualifications in most cases (the exception is Level 4, which is around 5\% more likely to be employed compared with Level 3). It is worth noting that the employment ratios for both males and females are around $90 \%$ for those finishing at Level 3.

[^16]Table A4.7: Sample size at ages 26 and 30 by qualifications obtained

|  | Age 26 regression sample |  | Age 30 regression sample |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Women | Men | Women | Men |
| Level 3 | 140,544 | 121,214 | 25,571 | 23,235 |
| Level 4 | 4,172 | 6,617 | 883 | 1,177 |
| Level 4 plus Level 5 | 161 | 638 | 26 | 103 |
| Level 4 plus FD | 107 | 258 | / | / |
| Level 4 plus Level 6 | 1,996 | 2,480 | 361 | 330 |
| Level 5 | 8,994 | 2,659 | 1,490 | 547 |
| Level 5 plus FD | 29 | 22 | / | / |
| Level 5 plus Level 6 | 2,927 | 2,671 | 455 | 320 |
| Foundation degree (FD) | 4,926 | 4,397 | 530 | 468 |
| FD plus Level 6 | 5,950 | 5,369 | 441 | 434 |
| Level 6 | 274,501 | 209,472 | 45,627 | 35,502 |
| Total | 444,307 | 355,797 | 75,404 | 62,152 |

Note: this table shows the cell sizes used in the above regression analysis.

[^0]:    ${ }^{1}$ J. Britton, L. Dearden, L. van der Erve and B. Waltmann (2020), The Lifetime Returns to Undergraduate Degrees, Department for Education Report.

[^1]:    ${ }^{2}$ The National Pupil Database contains data on pupils during their school years; the Individualised Learner Record gives further education data; and higher education records are taken from Higher Education Statistics Agency data.

[^2]:    ${ }^{3}$ We exclude individuals with post-18 courses in more than two levels because there are too few observations to be able to accurately estimate the returns to these educational pathways. We exclude apprenticeships as a distinct route which we are not considering in this analysis since our aim was to compare those who took the FE versus HE routes. We exclude postgraduate degrees to ensure we are comparing the earnings of those who took FE qualifications with those whose highest level of qualification is Level 6. As degrees offer a higher likelihood of progressing to postgraduate study, we are therefore not estimating the 'option value' of a degree for enabling further study.

[^3]:    ${ }^{4}$ Of those who undertake a Level 4 qualification after Level 6, there is variation in the type of qualifications taken, although the two most common are teaching-related: an Award in Preparing to Teach in the Lifelong Learning Sector ( $23 \%$ of learners in this group) and a Certificate in Teaching English to Speakers of Other Languages ( $16 \%$ of learners).

[^4]:    ${ }^{5}$ In Appendix A1, for comparison purposes, we present a range of summary statistics on the educational attainment, earnings and characteristics of the entire 2006 GCSE cohort rather than just a subset of learners.

[^5]:    Source: Linked NPD-ILR-HESA-HMRC data. Sample based on final column of Table 1.

[^6]:    ${ }^{6}$ A range of papers compare the returns from different educational trajectories over the life cycle, including J. Britton, L. Dearden, L. van der Erve and B. Waltmann (2020), The Lifetime Returns to Undergraduate Degrees, Department for Education Report; E. A. Hanushek, G. Schwert, L. Woessmann and L. Zhang (2017), General education, vocational education, and labor-market outcomes over the life-cycle, Journal of Human Resources,

[^7]:    52(1): 49-88; and G. Brunello and L. Rocco (2017), The labour market effects of academic and vocational education over the life cycle: evidence from a British cohort, Journal of Human Capital, 11(1): 106-166.
    ${ }^{7}$ As data on self-employment earnings is not available for all our cohorts, our estimates are based on PAYE earnings only. In Appendix A4 (Tables A4.3 and A4.4), we show the sensitivity of estimates at age 30 (i.e. for one cohort) for including and excluding self-employment earnings. This only has a small effect on estimated returns.
    ${ }^{8}$ For completeness, we have also estimated the conditional probability of being employed based on educational attainment. These results are presented Tables A4.5 and A4.6 in Appendix A4.

[^8]:    ${ }^{9}$ We chose these two ages since age 26 is the latest age at which we have earnings data available for every GCSE cohort ( $2001 / 02$ to $2005 / 06$ ) in our sample, while age 30 is the latest age for which we have earnings data available for at least one cohort (the 2001/02 GCSE cohort).
    ${ }^{10}$ Specifically, this measure is an indicator of whether or not the individual was in paid work at any point in the previous year.
    ${ }^{11}$ A full list of controls is provided in Appendix A3.
    ${ }^{12}$ It is worth noting the conditional estimate of 13.2 log points for men at age 30 , suggesting a 'return' to Level 6 qualifications of around $14 \%$, which is considerably higher than the estimated returns of $6 \%$ for men in C.
    Belfield, J. Britton, F. Buscha, L. Dearden, M. Dickson, L. van der Erve, L. Sibieta, A. Vignoles, I. Walker and Y. Zhu (2018), The Impact of Undergraduate Degrees on Early-Career Earnings, Department for Education Report. This is for several reasons, including: the 'treated' group is different here (i.e. 'Level 6 only' does not include those who progressed from Levels $4 / 5 /$ foundation degree to Level 6 ; it does not include anyone doing

[^9]:    lower-level qualifications in HE; and also it does not include people who go on to complete postgraduate degrees); the 'control' group here is different (it includes Level 3 only, and does not include sub-degree levels); the treatment of dropouts is different (this includes dropouts in the 'control' group, where Belfield et al. included dropouts in the 'treated' group); there are fewer conditioning variables because of the desire in this context to have a parsimonious set of controls across individuals with very different educational trajectories up to age 19 (most notably, Belfield et al. included a wide range of A Level controls which is not possible here because so many of the people taking FE routes did not take A Levels). The most important of these differences is the treatment of dropouts, which is a very complex issue in this context due to how this is measured across the different qualifications in the different datasets.
    ${ }^{13}$ The size of the final regression sample (800,104 observations) is smaller than the final earnings sample reported in Table 1 (959,329 observations) for three reasons: (i) only individuals with positive reported earnings at age 26 are included in the regression sample; (ii) individuals with key missing variables are omitted from the regression sample; and (iii) we exclude individuals with extreme earnings (i.e. below the $1^{\text {st }}$ percentile and above the $99^{\text {th }}$ percentile) from the regression sample.

[^10]:    ${ }^{14}$ We show raw average earnings of individuals whose highest educational attainment is Level 3. We adjust average earnings for all of the other qualifications based on our regression estimates. This uses the regression coefficient multiplied by earnings of the baseline group (i.e. those with a Level 3 qualification only) to calculate average or expected earnings for each group.

[^11]:    ${ }^{15}$ J. Britton, L. Dearden, L. van der Erve and B. Waltmann (2020), The Lifetime Returns to Undergraduate Degrees, Department for Education Report.
    ${ }^{16} \mathrm{HNC}$ in engineering is the most common. Related courses observed are HNCs in electrical, mechanical and civil engineering.
